Applicant(s)

KONNO, TAKESHI

Examiner

Monica A. Huson

Art Unit

1732

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

### Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

### Status

- 1) ☒ Responsive to communication(s) filed on 11 October 2006.
- 2a) ☒ This action is **FINAL**. 2b) ☐ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

### Disposition of Claims

- 4) ☒ Claim(s) 1-12 is/are pending in the application.
- 4a) Of the above claim(s) \_\_\_\_\_ is/are withdrawn from consideration.
- 5) ☐ Claim(s) \_\_\_\_\_ is/are allowed.
- 6) ☒ Claim(s) 1-12 is/are rejected.
- 7) ☐ Claim(s) \_\_\_\_\_ is/are objected to.
- 8) ☐ Claim(s) \_\_\_\_\_ are subject to restriction and/or election requirement.

### Application Papers

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☒ The drawing(s) filed on 14 November 2001 is/are: a) ☒ accepted or b) ☐ objected to by the Examiner.  
Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).  
Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

### Priority under 35 U.S.C. § 119

- 12) ☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☒ All b) ☐ Some \* c) ☐ None of:
- 1) ☒ Certified copies of the priority documents have been received.
  - 2) ☐ Certified copies of the priority documents have been received in Application No. \_\_\_\_\_.
  - 3) ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

\* See the attached detailed Office action for a list of the certified copies not received.

### **DETAILED ACTION**

This office action is in response to the Amendment filed 11 October 2006.

#### ***Claim Rejections - 35 USC § 102***

The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

A person shall be entitled to a patent unless –  
(b) the invention was patented or described in a printed publication in this or a foreign country or in public use or on sale in this country, more than one year prior to the date of application for patent in the United States.

Claim 9 is rejected under 35 USC 102(b) as being anticipated by Hunkar (U.S. Patent 3,941,534). Hunkar shows that it is known to carry out a method for controlling an injection molding machine in order to control the movement of a molten resin in a heating cylinder of the injection molding machine, the injection molding machine including a screw arranged within the heating cylinder to be rotatable and to be linearly movable and having a flight of a pitch P, the molten resin being moved in a forward direction during a plasticization process and an injection process (Abstract; Column 7, lines 13-27; Column 8, lines 28-43), the method comprising the steps of linearly moving the screw backwards relative to the forward feeding direction of the molten resin at a constant backward speed (Column 6, lines 45-48; Column 8, lines 16-18; Column 10, lines 6-19; Column 28, lines 24-35); controlling density distribution of molten resin at a nose portion of the screw while moving the screw backwards (Column 6, lines 50-58; Column 27, lines 37-63); and controlling a rotation speed of the screw based on a constant backward speed of the screw, wherein the controlling comprises simultaneously rotating the screw in the forward feeding direction at a rotation speed corresponding to the constant backward speed, after completion of the measuring process and

before starting the injection process (Column 9, lines 61-68; Column 28, lines 10-35).

***Claim Rejections - 35 USC § 103***

The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

Claims 1-8 and 10-12 are rejected under 35 U.S.C. 103(a) as being unpatentable over Shimizu (U.S. Patent 4,879,077), in view of Hunkar. Regarding Claim 1, Shimizu shows the basic process, including controlling an injection molding machine including a heating cylinder and a screw disposed in the heating cylinder (Column 3, lines 46-47), performing a plasticization/measuring process and an injection process (Column 2, lines 60), controlling a rotation speed R of the screw based on a constant backward speed V of the screw (Column 9, lines 61-68; Column 28, lines 10-35), wherein the controlling comprises defining a synchronization ratio of a rotation speed of the screw, so that the position of a flight of the screw does not apparently move relative to a constant speed of the screw (Figures 3-5; Column 2, lines 58-65), and defining a rotation speed of the screw by dividing the backward speed of the screw by the pitch of the flight of the screw (Column 2, lines 44-57; It is interpreted that the control equation applies to backward movement of the screw since backward movement is controlled in a similar fashion as frontward movement is controlled.). The examiner notes that a specific "synchronization ratio" is not explicitly defined in Shimizu, however, it would have been obvious to one of ordinary skill in the art at the time the invention was made to assign a value of 100% when the screw rotation and linear movement are perfectly synchronized, i.e. when the position of the flight does not move. The examiner

also notes that Shimizu does not explicitly define an arbitrary synchronization ratio, as used in the claimed formula. However, since the arbitrary synchronization ratio cannot alter how the process steps are to be performed to achieve the utility of the invention, it is herein addressed as nonfunctional descriptive material (MPEP 2106 VI.). Shimizu does not show controlling a density distribution of molten resin at a nose portion of the screw while moving the screw backwards or moving the screw backwards at a constant speed while rotating it after completion of the injection process. Hunkar shows that it is known to carry out a method including controlling a density distribution of molten resin at a nose portion of the screw while moving the screw backwards (Column 6, lines 50-58; Column 27, lines 37-63), and moving the screw backwards at a constant speed while rotating it after completion of the measuring process and before starting the injection process (Column 6, lines 45-48; Column 8, lines 16-18; Column 10, lines 6-19; Column 28, lines 24-35). Hunkar and Shimizu are combinable because they are concerned with a similar technical field, namely, methods of controlling molding operations. It would have been prima facie obvious to one of ordinary skill in the art at the time the invention was made to use Hunkar's control parameters during Shimizu's molding process in order to insure formation of an article which meets end-use specifications that are dependent upon density of the molding material.

Regarding Claim 2, Shimizu shows the basic process as claimed as discussed above, however Shimizu does not explicitly show variations of the synchronization of the screw rotation and linear movement. However, it would have been obvious to one of ordinary skill in the art at the time the invention was made to realize that if a synchronization ratio is less than 100%, the screw is rotated more slowly than the backward speed of the screw and that if the synchronization ratio is more than 100%, the screw is rotated faster than the backward speed of the screw. It would have been obvious to one of ordinary

Art Unit: 1732

skill in the art at the time the invention was made to vary Shimizu's synchronization ratio of the screw's rotation speed and linear speed during his molding process in order to achieve better measuring and melting of the material therein.

Regarding Claim 3, Shimizu shows the basic process as claimed, including a process using a heating cylinder, a screw disposed in a heating cylinder (Column 3, lines 46-47), a first driving source for driving the screw in an axial direction, a second driving source for rotating the screw (Column 4, lines 1-5, 18-27), position detecting means for detecting the axial position of the screw (Column 5, lines 42-51), rotation-speed detecting means for detecting the rotation speed of the screw (Column 4, lines 49-54), and a controller for controlling the first driving source and the second driving source dependent on the detecting signals transmitted from the position detecting means (Column 5, lines 47-51) and the rotation-speed detecting means (Column 4, 60-65). Shimizu also shows a plasticization/measuring process and an injection process (Column 2, lines 60), comprising the steps of, controlling a rotation speed  $R$  of the screw based on a constant backward speed  $V$  of the screw (Column 9, lines 61-68; Column 28, lines 10-24) defining a synchronization ratio of a rotation speed of the screw, so that the position of a flight of the screw does not apparently move relative to a constant speed of the screw (Figures 3-5; Column 2, lines 58-65), and defining a rotation speed of the screw by dividing the backward speed of the screw by the pitch of the flight of the screw (Column 2, lines 44-57). The examiner notes that a specific "synchronization ratio" is not explicitly defined in Shimizu, however, it would have been obvious to one of ordinary skill in the art at the time the invention was made to assign a value of 100% when the screw rotation and linear movement are perfectly synchronized. The examiner also notes that Shimizu does not explicitly define an arbitrary synchronization ratio, as used in the claimed formula. However, since the arbitrary synchronization ratio cannot alter

Art Unit: 1732

how the process steps are to be performed to achieve the utility of the invention, it is herein addressed as nonfunctional descriptive material (MPEP 2106 VI.). Shimizu does not show controlling a density distribution of molten resin at a nose portion of the screw while moving the screw backwards or moving the screw backwards at a constant speed while rotating it after completion of the injection process. Hunkar shows that it is known to carry out a method including controlling a density distribution of molten resin at a nose portion of the screw while moving the screw backwards (Column 6, lines 50-58; Column 27, lines 37-63), and moving the screw backwards at a constant speed while rotating it after completion of the measuring process and before starting the injection process (Column 6, lines 45-48; Column 8, lines 16-18; Column 10, lines 6-19; Column 28, lines 24-35). It would have been prima facie obvious to one of ordinary skill in the art at the time the invention was made to use Hunkar's control parameters during Shimizu's molding process in order to insure formation of an article which meets end-use specifications that are dependent upon density of the molding material.

Regarding Claim 4, Shimizu shows the basic process as claimed as discussed above, however Shimizu does not explicitly show variations of the synchronization of the screw rotation and linear movement. However, it would have been obvious to one of ordinary skill in the art at the time the invention was made to realize that if a synchronization ratio is less than 100%, the screw is rotated more slowly than the backward speed of the screw and that if the synchronization ratio is more than 100%, the screw is rotated faster than the backward speed of the screw. It would have been obvious to one of ordinary skill in the art at the time the invention was made to vary Shimizu's synchronization ratio during his molding process in order to achieve better measuring and melting of the material therein.

Regarding Claim 5, Shimizu shows the basic process as claimed, including controlling an injection molding machine including a heating cylinder

and a screw disposed in the heating cylinder (Column 3, lines 46-47), performing a plasticization/measuring process and an injection process (Column 2, line 60), controlling a rotation speed  $R$  of the screw based on constant linear backward speed  $V$  of the screw (Column 9, lines 61-68; Column 28, lines 10-35, wherein the controlling comprises defining a synchronization ratio of a rotation speed of the screw, so that the position of a flight of the screw does not apparently move relative to a constant linear backward speed of the screw (Column 2, lines 58-65), and defining a rotation speed of the screw by dividing the backward speed of the screw by the pitch of the flight of the screw (Column 2, lines 44-57). The examiner notes that a specific "synchronization ratio" is not explicitly defined in Shimizu, however, it would have been obvious to one of ordinary skill in the art at the time the invention was made to assign a value of 100% when the screw rotation and linear movement are perfectly synchronized. The examiner also notes that Shimizu does not explicitly define an arbitrary synchronization ratio, as used in the claimed formula. However, since the arbitrary synchronization ratio cannot alter how the process steps are to be performed to achieve the utility of the invention, it is herein addressed as nonfunctional descriptive material (MPEP 2106 VI.). Shimizu does not show controlling a density distribution of molten resin at a nose portion of the screw while moving the screw backwards or moving the screw backwards at a constant speed while rotating it after completion of the injection process. Hunkar shows that it is known to carry out a method including controlling a density distribution of molten resin at a nose portion of the screw while moving the screw backwards (Column 6, lines 50-58; Column 27, lines 37-63), and moving the screw backwards at a constant speed while rotating it after completion of the measuring process and before starting the injection process (Column 6, lines 45-48; Column 8, lines 16-18; Column 10, lines 6-19; Column 28, lines 24-35). It would have been prima facie obvious to one of ordinary skill in the art at the time the invention

was made to use Hunkar's control parameters during Shimizu's molding process in order to insure formation of an article which meets end-use specifications that are dependent upon density of the molding material.

Regarding Claim 6, Shimizu shows the basic process as claimed as discussed above, however Shimizu does not explicitly show variations of the synchronization of the screw rotation and linear movement. However, it would have been obvious to one of ordinary skill in the art at the time the invention was made to realize that if a synchronization ratio is less than 100%, the screw is rotated more slowly than the backward speed of the screw and that if the synchronization ratio is more than 100%, the screw is rotated faster than the backward speed of the screw. It would have been obvious to one of ordinary skill in the art at the time the invention was made to vary Shimizu's synchronization ratio during his molding process in order to achieve better measuring and melting of the material therein.

Regarding Claim 7, Shimizu shows the basic process as claimed, including a process using a heating cylinder, a screw disposed in a heating cylinder (Column 3, lines 46-47), a first driving source for driving the screw in an axial direction, a second driving source for rotating the screw (Column 4, lines 1-5, 18-27), position detecting means for detecting the axial position of the screw (Column 5, lines 42-51), rotation-speed detecting means for detecting the rotation speed of the screw (Column 4, lines 49-54), and a controller for controlling the first driving source and the second driving source dependent on the detecting signals transmitted from the position detecting means (Column 5, lines 47-51) and the rotation-speed detecting means (Column 4, 60-65). Shimizu also shows a plasticization/measuring process and an injection process (Column 2, line 60), comprising the steps of controlling a rotation speed  $R$  of the screw based on a constant linear backward speed  $V$  of the screw (Column 9, lines 61-68; Column 28, lines 10-35), wherein the controlling comprises defining a synchronization ratio of a rotation speed of the screw, so

that the position of a flight of the screw does not apparently move relative to a constant linear backward speed of the screw (Column 2, lines 58-65), and defining a rotation speed of the screw by dividing the backward speed of the screw by the pitch of the flight of the screw (Column 2, lines 44-57). The examiner notes that a specific "synchronization ratio" is not explicitly defined in Shimizu, however, it would have been obvious to one of ordinary skill in the art at the time the invention was made to assign a value of 100% when the screw rotation and linear movement are perfectly synchronized. The examiner also notes that Shimizu does not explicitly define an arbitrary synchronization ratio, as used in the claimed formula. However, since the arbitrary synchronization ratio cannot alter how the process steps are to be performed to achieve the utility of the invention, it is herein addressed as nonfunctional descriptive material (MPEP 2106 VI.). Shimizu does not show controlling a density distribution of molten resin at a nose portion of the screw while moving the screw backwards or moving the screw backwards at a constant speed while rotating it after completion of the injection process. Hunkar shows that it is known to carry out a method including controlling a density distribution of molten resin at a nose portion of the screw while moving the screw backwards (Column 6, lines 50-58; Column 27, lines 37-63), and moving the screw backwards at a constant speed while rotating it after completion of the measuring process and before starting the injection process (Column 6, lines 45-48; Column 8, lines 16-18; Column 10, lines 6-19; Column 28, lines 24-35). It would have been prima facie obvious to one of ordinary skill in the art at the time the invention was made to use Hunkar's control parameters during Shimizu's molding process in order to insure formation of an article which meets end-use specifications that are dependent upon density of the molding material. Furthermore, Shimizu shows the basic process as claimed as discussed above, but does not explicitly show variations of the synchronization of the screw rotation. However it would have been obvious to one of ordinary

skill in the art at the time the invention was made to realize that if a synchronization ratio is less than 100%, the screw is rotated more slowly than the backward speed of the screw and that if the synchronization ratio is more than 100%, the screw is rotated faster than the backward speed of the screw. It would have been obvious to one of ordinary skill in the art at the time the invention was made to vary Shimizu's synchronization ratio during his molding process in order to achieve better measuring and melting of the material therein.

Regarding Claim 8, Shimizu shows the basic process as claimed as discussed above, however Shimizu does not explicitly show variations of the synchronization of the screw rotation. However, it would have been obvious to one of ordinary skill in the art at the time the invention was made to realize that if a synchronization ratio is less than 100%, the screw is rotated more slowly than the backward speed of the screw and that if the synchronization ratio is more than 100%, the screw is rotated faster than the backward speed of the screw. It would have been obvious to one of ordinary skill in the art at the time the invention was made to vary Shimizu's synchronization ratio during his molding process in order to achieve better measuring and melting of the material therein.

Regarding Claim 10, Shimizu shows the process as claimed as discussed above in the rejection of claim 9, including showing that it is known to control an injection molding operation by performing a plasticization/measuring process and an injection process (Column 2, lines 18-26). Shimizu also shows that it is known to define a synchronization ratio of a rotation speed of the screw, so that the position of a flight of the screw does not apparently move relative to a speed of the screw (Column 2, lines 58-65), and to define a rotation speed of the screw by dividing the linear (backward, as in Yamazaki) speed of the screw by the pitch of the flight of the screw (Column 2, lines 44-57). The examiner notes that a specific "synchronization ratio" is not explicitly defined

Art Unit: 1732

in Shimizu, however, it would have been obvious to one of ordinary skill in the art at the time the invention was made to assign a value of 100% when the screw rotation and linear movement are perfectly synchronized. It would have been obvious to one of ordinary skill in the art at the time the invention was made to realize that if a synchronization ratio is less than 100%, the screw is rotated more slowly than the backward speed of the screw and that if the synchronization ratio is more than 100%, the screw is rotated faster than the backward speed of the screw. It would have been obvious to one of ordinary skill in the art at the time the invention was made to vary Shimizu's synchronization ratio of the screw's rotation speed and linear speed during his molding process in order to achieve better measuring and melting of the material therein.

Regarding Claim 11, Shimizu shows the process as claimed as discussed above in the rejection of claim 10, including showing that it is known to define a rotation speed of the screw by dividing the backward speed of the screw by the pitch of the flight of the screw (Column 2, lines 44-57). Furthermore, the examiner also notes that Shimizu does not explicitly define a synchronization ratio, as used in the formula in Claim 11. However, since the synchronization ratio of Claim 11 cannot alter how the process steps are to be performed to achieve the utility of the invention, it is herein addressed as nonfunctional descriptive material (MPEP 2106 VI.).

Regarding Claim 12, Shimizu shows the process as claimed as discussed above in the rejection of claim 10, including showing that it is known to define a synchronization ratio of a rotation speed of the screw, so that the position of a flight of the screw does not apparently move relative to a speed of the screw (Column 2, lines 58-65). The examiner notes that a specific "synchronization ratio" is not explicitly defined in Shimizu, however, it would have been obvious to one of ordinary skill in the art at the time the invention was made to assign a value of 100% when the screw rotation and linear movement are perfectly

synchronized. It would have been obvious to one of ordinary skill in the art at the time the invention was made to realize that if a synchronization ratio is less than 100%, the screw is rotated more slowly than the backward speed of the screw and that if the synchronization ratio is more than 100%, the screw is rotated faster than the backward speed of the screw. It would have been obvious to one of ordinary skill in the art at the time the invention was made to vary Shimizu's synchronization ratio of the screw's rotation speed and linear speed during his molding process in order to achieve better measuring and melting of the material therein.

### ***Response to Arguments***

Applicant's arguments filed 11 October 2006 have been fully considered but they are not persuasive.

Applicant contends that Hunkar does not show all of the elements of any of the pending claims. It is noted that Hunkar alone is only applied to claim 9.

Applicant contends that Hunkar's control process cannot take place after the measuring process and before the injection process. This is not persuasive as some measuring takes place prior to the plasticization process in order to avoid overloading the plasticizer.

Applicant contends that "since the temperature of the heating cylinder is influenced by the change of the outside temperature, it is impossible to control precisely the density of the molten resin using Hunkar's technique." (see response, page 15, para. 2). However, in his preceding paragraph, applicant states "the technique of Hunkar, which controls the density of the molten resin...". It is maintained by the examiner that Hunkar shows controlling density of the resin.

Applicant contends that in Hunkar, "there is no disclosure or suggestion of...controlling a density distribution of molten resin at a nose portion of the screw" (see page 16, para. 2). However, on page 15, paragraph 1, applicant

states “the technique of Hunkar, which controls the density of the molten resin...”. It is maintained by the examiner that Hunkar shows controlling density of the resin at a nose portion of the screw.

Applicant contends that in Hunkar, “there is no disclosure that the ‘rotation speed’ is ‘corresponding to the constant backward speed’ or that the correspondence is controlled.” (see response, page 17, para. 1) This is not persuasive because controlled correspondence is not particularly claimed. Furthermore, two values that correspond to each other are not necessarily dependent upon each other. The claim does not require the rotation speed to be a function of the backward speed. The claim merely requires a rotation speed corresponding (in an unspecified manner) to a backward speed. In other words, the two “corresponding” variables could be otherwise independent from each other, save their values at a common time period.

Applicant contends that Hunkar does not show a synchronization ratio. This is not persuasive because although Hunkar does not identify it as a “synchronization ratio”, he discloses the same mathematical relationship at Column 2, lines 44-65.

Applicant contends that Shimizu does not show the instant invention because he does not show the idea that the screw moves backwards at a constant speed. This is not persuasive because Shimizu was not cited to show this step.

### **Conclusion**

Applicant's amendment necessitated the new ground(s) of rejection presented in this Office action. Accordingly, **THIS ACTION IS MADE FINAL**. See MPEP § 706.07(a). Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a).

A shortened statutory period for reply to this final action is set to expire **THREE MONTHS** from the mailing date of this action. In the event a first reply

is filed within TWO MONTHS of the mailing date of this final action and the advisory action is not mailed until after the end of the THREE-MONTH shortened statutory period, then the shortened statutory period will expire on the date the advisory action is mailed, and any extension fee pursuant to 37 CFR 1.136(a) will be calculated from the mailing date of the advisory action. In no event, however, will the statutory period for reply expire later than SIX MONTHS from the date of this final action.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to Monica A. Huson whose telephone number is 571-272-1198. The examiner can normally be reached on Monday-Friday 7:30am-4:00pm.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Christina Johnson can be reached on 571-272-1176. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.
